

A young girl with brown hair, wearing a yellow tank top and colorful patterned shorts, is sitting on a white textured rug. She is playing with various colorful geometric toys, including triangles and pyramids in shades of green, yellow, red, and orange. Some of the toys are wooden, while others are plastic. The background is a dark grey carpet.

PEDIATRIC RESUSCITATION

Mioara Manole, MD

Pediatric Emergency Medicine
Children's Hospital of Pittsburgh

Out of hospital cardiac arrest

Not witnessed (long time without CPR)

No preexisting conditions

Etiology: Respiratory

Bystander CPR late and less effective

In hospital cardiac arrest

Witnessed

Preexisting pathology

Etiology: Cardiac

Immediate high quality CPR

Pediatric Resuscitation
=PREVENTION

Respiratory failure

Shock

Effective and early CPR

Prearrest care- In hospital

- Medical rapid response teams
 - May prevent cardiac and respiratory arrest
- Pediatric early warning scores (PEWS)
 - May be used, but effectiveness not established

BLS

Respiratory failure- anticipate

- Increased respiratory rate
- Signs of respiratory distress
 - Nasal flaring
 - Retractions
 - Seesaw breathing
 - Grunting
- Diminished breath sounds
- Gaspings
- Cyanosis

Pediatric Anatomy & Physiology

Young infants

- obligate nose breathers, obstruction of nasal passages causes distress

Young children

- less reserve, deteriorate quickly

Children

- more flexible chest walls, less developed chest muscles, diaphragm more prone to fatigue

RESPIRATORY FAILURE OCCURS MORE COMMONLY IN CHILDREN

NOSE BREATHERS

LARGE TONGUE

SMALL AIRWAY

SOFT TRACHEA

**MUSCLE FATIGUE
EASIER**

**FREQUENT
VIRAL
RESPIRATORY
INFECTIONS**

INFANTS

Anticipate Pediatric airways of concern

- **Altered sensorium**
 - Upper airway relaxes
- **Extra soft airway tissue (Laryngomalacia)**
 - Obstruction with viral illnesses
- **Malformations of the tongue and mandible**
 - Down syndrome
- **Child with noisy breathing**
 - Croup, tracheitis, retropharyngeal abscess, burns, allergic reactions
- **Cervical spine immobilization**

Failproof interventions for respiratory distress

- Position of comfort: in mom's arms, sitting up
 - Stridor: Croup, tracheitis
- Nasal suctioning
 - Infants with bronchiolitis
- Oxygen
 - Nasal canula: infants with bronchiolitis
 - Blow by: older children
 - Face mask held by mom in front of the face

BLS

Shock- recognize

Compensated

- Tachycardia
- Cool pale extremities
- Prolonged cap refill
- Weak peripheral pulses
- Normal blood pressure

Decompensated

- Depressed mental status
- Decreased urinary output
- Tachycardia
- Weak central pulse
- Deterioration in color (mottling)

*No single sign confirms the diagnosis- integrate symptoms and signs

BLS

Hypotension: systolic blood pressure values

- Neonates <60 mm Hg
- Infants (1mo-1 year) <70 mm Hg
- Children (1-10 years) $<70 + 2(\text{age})$ mmHg (years)
- Adolescents (>10 years) <90 mm Hg

Prearrest care Septic shock

- Previous recommendation: early and rapid administration of IVF
- Current recommendations:
 - Administration of 20 ml/kg bolus is reasonable
 - Reassess after each bolus
 - Either crystalloids or colloids are effective
- Why the recommendations changed
 - One large study in a limited resource area showed increased mortality with 20-40 ml/kg fluid boluses when compared with maintenance fluid alone
 - Thus, in areas with no intensive care support (mechanical ventilation, pressors) gentle approach to intravenous fluids is recommended

Prearrest care

Hypovolemic shock

- Use crystalloids: lactated Ringer's or normal saline as the initial bolus
- Treat shock with 20 mL/Kg bolus even if blood pressure is normal
 - Compensated shock

Prearrest care Myocarditis

- Avert cardiac arrest
- Consider pre-cardiac arrest extracorporeal membrane oxygenation (ECMO) use

Pediatric cardiac arrest

- Respiratory
- Respiratory
- Respiratory
- Cardiac

Pediatric CPR

VENTILATIONS
ARE IMPORTANT

RATE FOR 2 RESCUERS
15:2

When do we
use adult
guidelines in
children?

- At Puberty
 - physical characteristics are easier to identify than specific ages
- Puberty:
 - Girls: Breast development
 - Boys: Axillary hair

BLS

Simultaneous actions

- Chest compressions- one rescuer
- Ventilations- another rescuer
- Monitor, defibrillator, iv, prepare medication- third rescuer

*ventilations are important in pediatrics: asphyxial cardiac arrests

BLS

Assure GOOD Quality of Compressions

- Push hard
 - 1/3 the AP diameter of the chest
 - 1 ½ in in infants= 4 cm
 - 2 in in children= 5 cm
- Push fast
 - 100 compressions/min
 - Rotate compressors every 2 minutes
- Allow full recoil
- Minimize interruptions
- Firm surface

*Don't hyperventilate

BLS

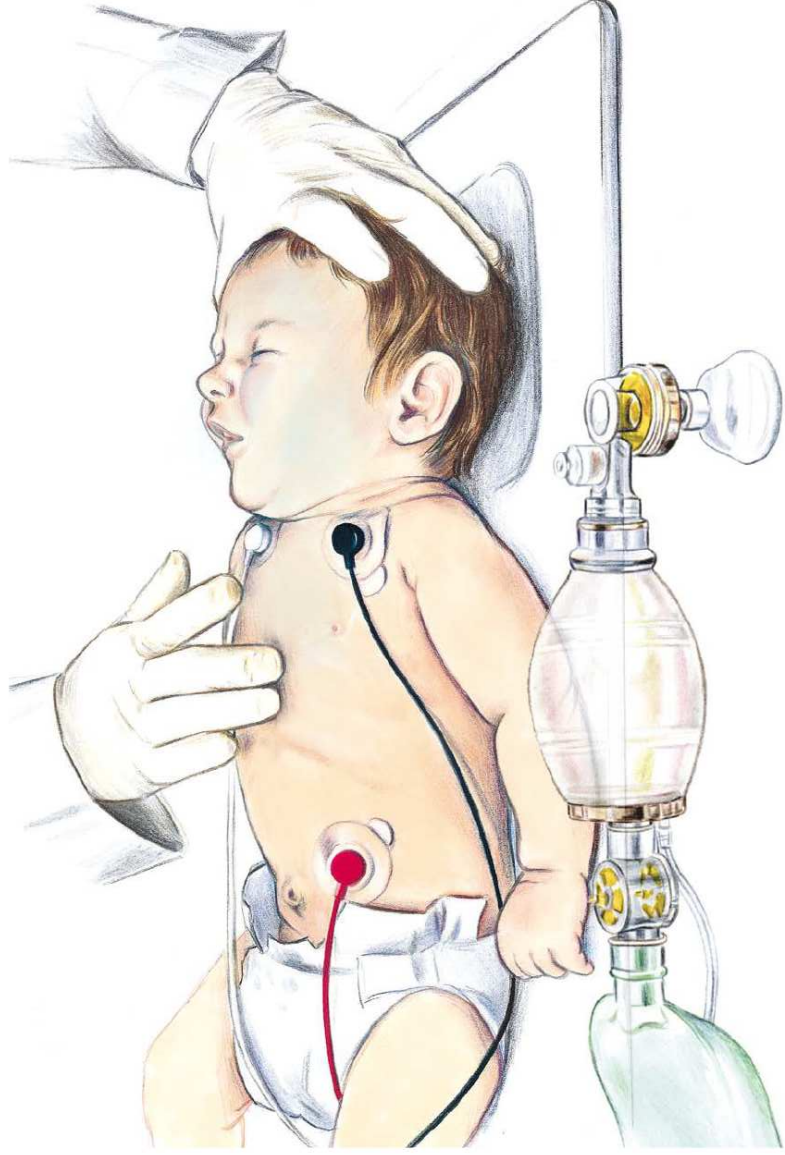

Compressions

- Is there a need to assist circulation
 - assure adequate oxygen & ventilation
 - HR < 60 with poor perfusion
- Chest compressions
 - 1 rescuer 30:2
 - 2 rescuer 15:2
 - 1/3 depth of chest

Two thumb-encircling hands chest compression in infant (2 rescuers).

**Two-finger chest compression technique in infant
(1 rescuer)**

BLS

Compressions in monitored patients

- Use end tidal CO₂ to guide chest compressions

BLS

Oropharyngeal and nasopharyngeal airways

- Oropharyngeal
 - Absent gag reflex
 - Use correct size
 - small may push tongue back
 - large may obstruct airway
- Nasopharyngeal
 - Gag reflex present
 - Use correct size
 - short is not effective
 - long may obstruct airway
 - Suction as needed: may become obstructed with secretions

BLS

Laryngeal Mask Airway (LMA)

- Acceptable to be used by experienced providers when:
 - Bag Valve Mask is ineffective
 - Endotracheal intubation is not possible

BLS Oxygen

- Reasonable to ventilate with 100% oxygen during CPR
- After return of spontaneous circulation, wean to O₂ Sat 94-99%

Why:

- *there is insufficient information on the optimal oxygen concentration
- *use enough oxygen to oxygenate but avoid hyperoxia

BLS

Pulse oximetry

- If the patient has a perfusing rhythm, monitor O₂ saturation with pulse oximeter

BLS

Bag-mask ventilation

Bag-mask ventilation might be safer than endotracheal intubation for

- Short periods
- During out-of-hospital resuscitation

*use proper mask

*provide tight seal

*assess effectiveness of ventilations- chest rise

BLS

Bag-mask ventilation

- *use only the force and tidal volume to make the chest rise visibly
 - avoid gastric inflation
- *inspiratory time 1 sec
 - Squeeze-release-release
- *if the child is intubated or LMA:
 - 1 breath every 6 seconds (10 breaths per minute)
- *if perfusing rhythm
 - 1 breath every 3-5 sec (12-20 breaths per minute)

BLS

Bag-mask ventilation

Two person BVM

- better seal

Cricoid pressure in the unresponsive victim (may require a 3rd person)

- reduces gastric inflation

- avoid excessive cricoid pressure (may obstruct trachea)

- *may need to discontinue during intubation (if view is distorted)

BLS

Ventilation with tracheostomy

- Ventilate through tracheostomy
- If ineffective: suction tracheostomy tube
- If suctioning ineffective:
 - replace tracheostomy tube
 - place endotracheal tube
- If nothing works
 - Mouth to stoma or mask to stoma ventilations
 - Occlude stoma and perform bag-mask ventilations

BLS

Endotracheal intubation

- Only if experienced
- Both cuffed and uncuffed tubes are ok
- Cuffed tubes may decrease risk of aspiration:
 - Cuff inflation pressure 20-25 mmHg
 - Formula:
 - Uncuffed $4 + \text{age}/4$
 - Cuffed 0.5 mm smaller

*think this way: start at 4 (uncuffed) in infants

BLS

Verify endotracheal tube position

- Bilateral chest movement
- Equal breath sounds
- End tidal monitor- color change or tracing
- Pulse oximeter read (if perfusing rhythm)
- Direct laryngoscopy (if uncertain)
- Chest x ray (in hospital)

*if end tidal CO₂ is not detected in CA, confirm tube position with direct laryngoscopy

*low pulmonary blood flow may cause absence of exhaled CO₂

Atropine for pre-medication during intubation

- Previous recommendations:
 - Use atropine
 - To prevent bradycardia (hypoxia, vagal reflex laryngoscopy)
- Current recommendations:
 - May be reasonable to use atropine
 - 0.02 mg/kg

BLS

Newborns CPR rates

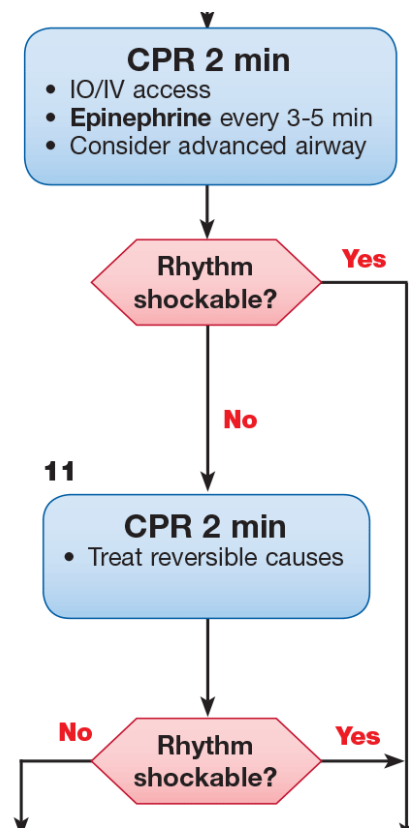

- 15:2 if resuscitated in the prehospital, ED, PICU

*newborn CPR is 3:1 in NICU or delivery room

*for ease of training, 15:2 is recommended

ACLS

Pulseless arrest- Asystole

Drug Therapy

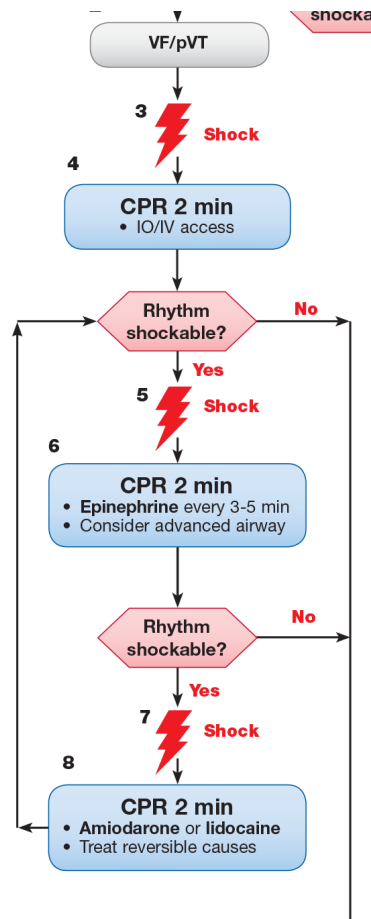

- **Epinephrine IO/IV dose:** 0.01 mg/kg (0.1 mL/kg of 1:10 000 concentration). Repeat every 3-5 minutes.
If no IO/IV access, may give endotracheal dose: 0.1 mg/kg (0.1 mL/kg of 1:1000 concentration).

Reversible Causes

- **Hypovolemia**
- **Hypoxia**
- **Hydrogen ion (acidosis)**
- **Hypoglycemia**
- **Hypo-/hyperkalemia**
- **Hypothermia**
- **Tension pneumothorax**
- **Tamponade, cardiac**
- **Toxins**
- **Thrombosis, pulmonary**
- **Thrombosis, coronary**

ACLS

Ventricular fibrillation

Shock Energy for Defibrillation

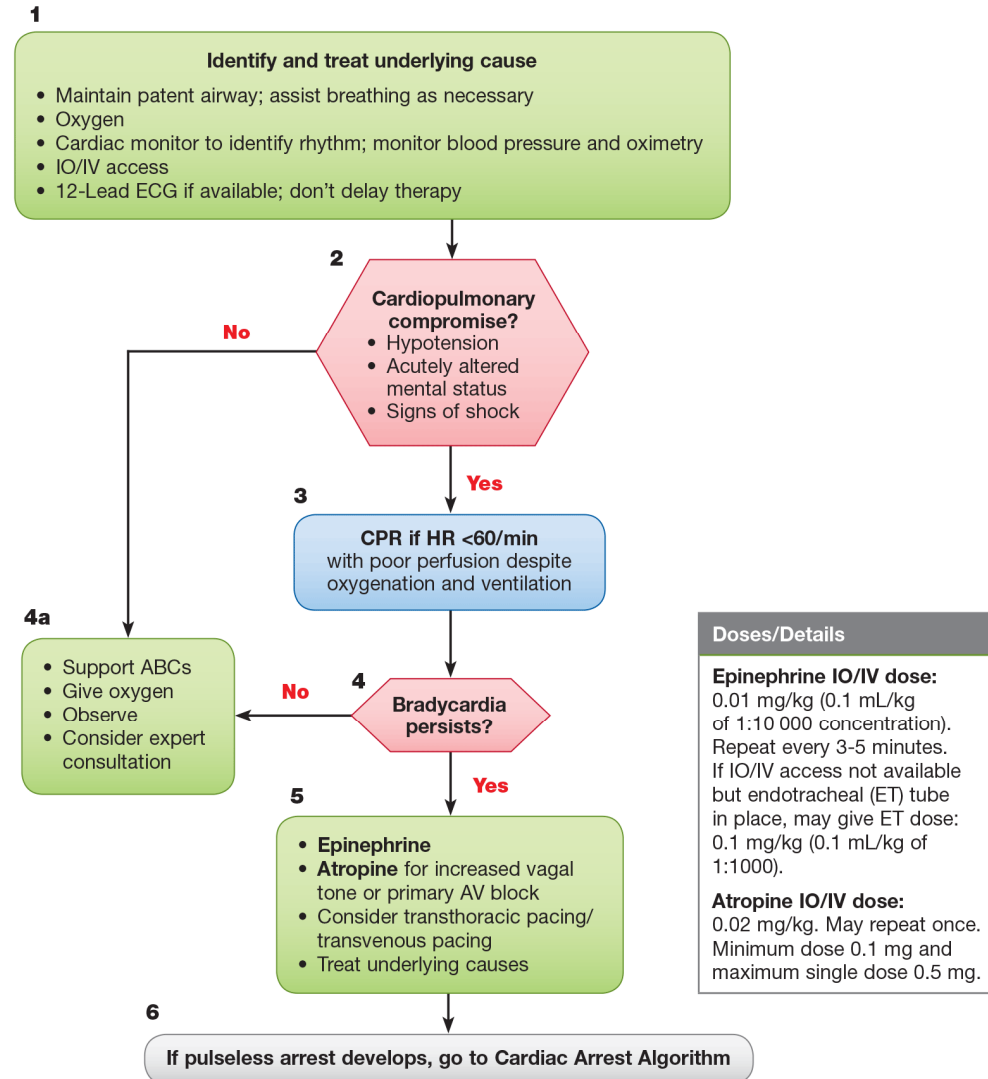

First shock 2 J/kg, second shock 4 J/kg, subsequent shocks ≥ 4 J/kg, maximum 10 J/kg or adult dose

Drug Therapy

- Epinephrine IO/IV dose:**
 0.01 mg/kg (0.1 mL/kg of 1:10 000 concentration). Repeat every 3-5 minutes.
 If no IO/IV access, may give endotracheal dose: 0.1 mg/kg (0.1 mL/kg of 1:1000 concentration).
- Amiodarone IO/IV dose:**
 5 mg/kg bolus during cardiac arrest. May repeat up to 2 times for refractory VF/pulseless VT.
- Lidocaine IO/IV dose:**
 Initial: 1 mg/kg loading dose.
 Maintenance: 20-50 mcg/kg per minute infusion (repeat bolus dose if infusion initiated >15 minutes after initial bolus therapy).

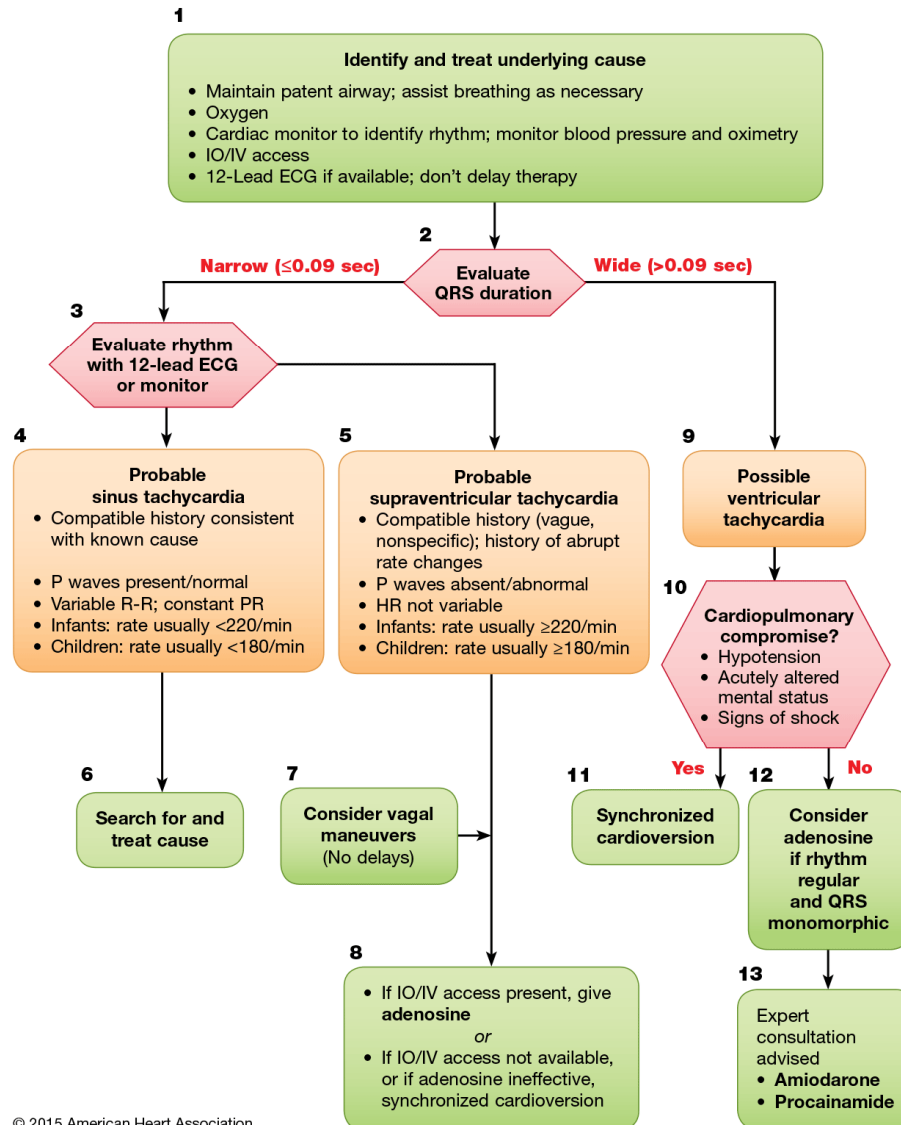

ACLS Bradycardia

Pediatric Bradycardia With a Pulse and Poor Perfusion Algorithm

ACLS Tachycardia with a pulse

Pediatric Tachycardia With a Pulse and Poor Perfusion Algorithm

Doses/Details
Synchronized Cardioversion
Begin with 0.5-1 J/kg; if not effective, increase to 2 J/kg. Sedate if needed, but don't delay cardioversion.
Drug Therapy
Adenosine IO/IV dose: First dose: 0.1 mg/kg rapid bolus (maximum: 6 mg). Second dose: 0.2 mg/kg rapid bolus (maximum second dose: 12 mg).
Amiodarone IO/IV dose: 5 mg/kg over 20-60 minutes or
Procainamide IO/IV dose: 15 mg/kg over 30-60 minutes
Do not routinely administer amiodarone and procainamide together.

ACLS

Special situations

- Trauma: do not hyperventilate
- Past history of cardiac condition: consider ECMO initiation
 - EMS: notify hospital to prepare
- Family presence should be encouraged whenever possible
- Termination of resuscitation efforts: no reliable predictors of outcome to guide termination of resuscitation efforts
 - Bystander CPR, short interval from collapse to CPR, witnessed collapse increase chances of successful resuscitation

Post resuscitation care

- Target normoxia
- Target normal end tidal CO₂
- Remove IO after other intravenous access is available
- Maintain blood pressure at > 5th percentile for age
 - Fluids, inotropic agents
- Temperature management
 - Avoid hyperthermia
 - 5 days of normothermia (36-37.5 C) *OR*
 - 2 days of hypothermia (32-34 C) + 3 days of normothermia (36-37.5 C)
- SIDS: refer families for screening of arrhythmia
